Forecasting HIV cases in Awka South (2025-2028)

Divine-Favour Ekemezie

December 2023

DATA PRESENTATION AND ANALYSIS

Data presentation and analysis will be comprehensively discussed in this section. Starting with presenting the data on HIV-positive cases in Awka South sourced secondarily from Amaku teaching hospital, Awka, to presenting relevant plots and forecasting the prevalence rate of HIV in Awka South, and hence drawing necessary conclusions.

The table below shows the HIV cases in Awka South from the year 2014 to 2023.

Table 1: HIV-positive cases in Awka South from the year 2014 to 2023

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Average
2014	299	185	225	127	233	260	155	164	243	163	223	292	214.0833
2015	238	186	276	145	229	194	190	188	240	188	227	285	215.5
2016	252	195	291	138	229	208	158	172	170	205	266	307	215.9167
2017	266	170	250	166	222	254	152	273	175	177	247	304	221.3333
2018	302	171	245	155	264	180	161	210	164	198	246	305	216.75
2019	214	183	230	178	222	197	185	248	165	214	202	231	205.75
2020	173	168	204	187	191	191	180	180	210	178	170	176	184
2021	186	173	176	176	185	165	173	180	167	174	177	169	175.0833
2022	181	180	185	159	170	171	155	195	185	157	186	181	175.4167
2023	200	174	170	190	194	180	161	161	173	174	178	188	178.5833

Following the data are the plots of the yearly HIV cases of HIV alongside it's representation with the normal curve.

The graph of yearly average HIV cases from 2014 to 2023 shows a clear declining trend in the number of HIV-positive cases over time. HIV cases peaked around 2018, followed by a noticeable decline, particularly from 2019 onwards. This downward trend may reflect the impact of enhanced public health interventions, increased awareness, or improved treatment programs. The earlier portion of the dataset (2014 to 2018) shows some fluctuations, with

Yearly Average of HIV Cases (2014–2023)

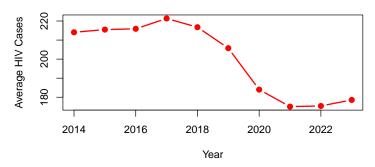

Figure 1: Yearly Average of HIV cases

periods of rising and stabilizing case averages. Overall, the trend from 2019 onwards suggests gradual progress in reducing HIV cases in the region.

The Histogram of Yearly Average HIV Cases from 2010-2019 plot shows that the average number of HIV cases fluctuated between approximately 150 and 200 over the years, indicating some variation in yearly cases, though the overall trend remains relatively consistent without drastic increases or decreases.

1 Data Modelling and Fitting

This section encompasses the subjection of the HIV data to normality tests to determine if the data is considered normal or not. Several methods will be employed such as Shapiro-Wilk, Anderson Darling, Crammer Von Mises, and Lilliefors (Kolmogorov's Smirnov) tests, and then in order to visualize how well the data fits a normal distribution, a Q-Q plot alongside a histogram showing the normal curve will be established.

The table below shows the results from these tests.

Table 2: Normality Test Results

Test	Result	p-value
Shapiro-Wilk	0.97	0.0208
Anderson Darling	0.86	0237
Crammer Von Misses	0.12	0.0434
Kolmogorov Smirnov	0.08	0.0220

To assess the normality of the data, we test the following hypotheses:

Null hypothesis (H_0) : There is no significant difference between the observed data and the generated normal distribution.

Alternative hypothesis (H_1) : There is a significant difference between the observed data and the generated normal distribution.

Since the p-values for all the normality tests in Table 2 are less than 0.05, we will reject the null hypothesis. Thus, we conclude that there is a significant difference between the observed data and the normal distribution, indicating that the data does not have a normal distribution.

In this analysis, we will evaluate the accuracy of three models by employing three key metrics: Mean Absolute Percentage Error (MAPE), Mean Absolute Error (MAE), and Root Mean Squared Error (RMSE). By comparing these metrics across the models, we aim to identify the most effective model for forecasting the trend of HIV cases in Awka South.

Table 3: Model Fitting of the HIV Data

Model	MAE	RMSE	MAPE
Linear	28.12	37.51	14.0
Quadratic	28.79	37.21	14.38
Exponential	27.95	37.76	13.63

Based on the results obtained, it suggests that the changes in HIV cases over time follow an exponential pattern rather than a linear or quadratic trend. This generally implies that the number of cases increases or decreases at a consistent percentage rate, rather than by a fixed amount in each period.

2 ARIMA Forecasting

To model the data using ARIMA, it's essential to first determine whether the time series is stationary or non-stationary. This is done by analyzing the graphs of the Autocorrelation Function (ACF) and the Partial Autocorrelation Function (PACF).

The figure 2 indicates that the HIV case data exhibits short-term dependencies, with recent values (like those from the previous month) being strongly correlated with the current values. This is useful for fitting autoregressive (AR) models, as the PACF helps determine the appropriate number of lags to include, likely 1 or 2 in this case. It suggests that the current month's HIV cases can be effectively forecasted using data from recent months, while contributions from more distant periods are less significant for prediction. The ARIMA forecasting was conducted using the statistical tool R, which can be seen in the appendix.

PACF of HIV Cases

The table 4 above represents predicted HIV-positive case numbers from January 2024 to December 2026, derived from historical data spanning 2014 to 2023 and utilizing an ARIMA (0,1,1) model for projection. The point forecast provides the projected number of HIV-positive cases for each month, representing the model's most accurate estimate based on historical trends and patterns. The point forecast for January 2024 is 188.09, indicating that the model predicts around 188 HIV-positive cases for that month. By December 2026, the forecast drops to 169.90, suggesting a gradual decline in cases over time compared to previous years.

The confidence intervals as shown in the table above are 80% and 90%. These intervals depict the range at which the true value will fall. Lo 80 and Hi 80: This shows the 80% confidence interval, which simply explains that there is an 80% chance that the actual number of HIV-positive cases will fall within this range.

- For January, the 80% confidence interval is 150.89 to 225.30, indicating there is an 80% chance the actual number of cases will fall between 151 and 225.
- By the end of 2026, the 80% confidence interval is 118.18 to 221.63.

Lo 95 and Hi 95 represent the 95% confidence interval, indicating a wider range where the actual values are expected to fall with 95% confidence.

- The 95% confidence interval for January 2024 ranges from 131.20 to 244.99, indicating that with 95% confidence, the actual number of cases is expected to fall between 131 and 245.
- By December 2026, the 95% confidence interval ranges from 90.79 to 249.02, reflecting a broader range of uncertainty in the model's prediction.
